ABSTRACT

There is an urgent need to identify antivirals against the coronavirus SARS-CoV-2 in the current COVID-19 pandemic and to contain future similar emergencies early on. Specific side-chain cholesterol oxidation products of the oxysterols family have been shown to inhibit a large variety of both enveloped and non-enveloped human viral pathogens. Here we report on the in vitro inhibitory activity of the redox active oxysterol 27-hydroxycholesterol against SARS-CoV-2 and against one of the common cold agents HCoV-OC43 human coronavirus without significant cytotoxicity. Interestingly, physiological serum levels of 27-hydroxycholesterol in SARS-CoV-2 positive subjects were significantly decreased compared to the matched control group, reaching a marked 50% reduction in severe COVID-19 cases. Moreover, no correlation at all was observed between 24-hydroxycholesterol and 25-hydroxycholesterol serum levels and the severity of the disease. Opposite to that of 27-hydroxycholesterol was the behaviour of two recognized markers of redox imbalance, i.e. 7-ketocholesterol and 7β-hydroxycholesterol, whose serum levels were significantly increased especially in severe COVID-19. The exogenous administration of 27-hydroxycholesterol may represent in the near future a valid antiviral strategy in the worsening of diseases caused by present and emerging coronaviruses.

1. Introduction

The present COVID-19 pandemic caused by the coronavirus SARS-CoV-2 is yet another example of the dramatic impact of emerging viral infections on human morbidity and mortality worldwide. Currently, no specific drug for the new coronavirus is available and repurposing is the only strategy in place [1]. Clearly, there is an urgent need for drugs active against a wider number of viruses to contain future emergencies early on. Host directed therapy aims at targeting essential host factors for viral replication and triggering immune antiviral pathways [2]. Advantages of this approach include not only the possibility of targeting multiple viruses, but also an increased threshold to the emergence of resistance.

Selective cholesterol oxidation products, of the oxysterol family, which are ligands of Liver X Receptors (LXRs), have a well-recognized immunomodulatory role [3,4]. Oxysterols such as 25-hydroxycholesterol play a role in the regulation of immune function through the induction of anti-inflammatory responses [5]. Unfortunately, the use of cholesterol oxidation products in the treatment of immune-mediated diseases has been limited by their cytotoxicity and immune-suppressive effects [6]. However, recent findings suggest that cholesterol oxidation products may have a role in the regulation of immune function through the induction of anti-inflammatory responses [7]. The exogenous administration of 27-hydroxycholesterol may represent in the near future a valid antiviral strategy in the worsening of diseases caused by present and emerging coronaviruses.

Moreover, we analyzed the serum levels of 27OHC in 123 healthy in vitro infected, 10% (v/v) fetal bovine serum (Sigma). Cells Hep-2 (ATCC CCL-23) were propagated in Hep-2 and titrated by the indirect immunoperoxidase staining procedure as described elsewhere [19]. Viral titers were expressed as focus-forming unit (FFU) per ml. Viruses were stored at −80 °C.

2. Methods

2.1. Reagents

The oxysterol 27OHC complexed with 2-hydroxypropyl-β-cyclodextrin (2HP-βCD:27OHC) was kindly provided by Panoxyvir Ltd (Turin, Italy). The anti-RSV monoclonal antibody Ab35958 was purchased from Abcam (Cambridge, United Kingdom). The secondary antibody peroxidase-conjugated AffiniPure F(ab′)2 Fragment Goat Anti-Mouse IgG (H+L) was purchased from Jackson ImmunoResearch Laboratories Inc. (West Grove, PA, USA). The recombinant antibody mSIP-3022 against SARS-CoV-2 Spike was previously described [17].

2.2. Cell lines and viruses

Vero E6 cells (African green monkey kidney cells) (ATCC®-CCL-186) and human hepatocarcinoma HuH7 cells kindly provided by Ralf Bartenschläger (University of Heidelberg, Germany) were cultured in DMEM (Gibco) supplemented with 10% fetal bovine serum (Gibco). Human lung fibroblast MRC-5 (ATCC® CCL-171) and human epithelial cells Hep-2 (ATCC® CCL-23) were propagated in Dulbecco’s Modified Eagle Medium (DMEM; Sigma, St. Louis, MO, USA) supplemented with 1% (v/v) penicillin/streptomycin solution (Euroclone, Milan, Italy) and heat inactivated, 10% (v/v) fetal bovine serum (Sigma).

SARS-CoV-2 isolate IGECB_FVG_SS was obtained at IGECB as previously described [18]. Plaque assay was performed by incubating dilutions of SARS-CoV-2 on Vero E6 monolayers at 37 °C for 1 h. These were then washed with phosphate buffered saline (PBS) and overlaid with DMEM 2% FBS containing 1.5% carboxymethylcellulose for 3 days. Cells were then fixed with 3.7% paraformaldehyde (PFA) and stained with crystal violet 1%.

Human coronavirus strain OC43 (HCoV-OC43) (ATCC® VR-1558) was purchased from ATCC (American Type Culture Collection, Rockville, MD, USA) and propagated in MRC-5 cells, at 33 °C, in a humidified 5% CO2 incubator. When the full cytopathic effect (CPE) developed, cells and supernatants were harvested, pooled, frozen, and thawed three times, then clarified and aliquoted. The virus was stored at −70 °C. CoV titers were determined by the standard plaque method. Briefly, MRC-5 cells were seeded 2 days before infection in 96-well plates, reaching 60%–70% confluence at the time of infection. The viral suspension was serially diluted in DMEM supplemented with 2% fetal bovine serum and inoculated; the infected wells were incubated at 33 °C for 1 h, allowing viruses to attach and enter the cells. After this time, cells were washed with medium, and overlaid with a 1:1 combination of 1.6% SeaPlate Agarose (BioWhittaker Molecular Applications) and 2 × DMEM medium (Gibco BRL) as described elsewhere [8]. The plates were incubated at 33 °C for 3 days. After incubation, the plates were fixed and stained as described elsewhere [8], and the number of plaques formed was counted; viral titers were expressed in terms of plaque forming units per ml (PFU/ml). Respiratory syncytial virus (RSV) strain A2 (ATCC VR-1540) was propagated in Hep-2 and titrated by the indirect immunoperoxidase staining procedure as described elsewhere [19]. Viral titers were expressed as focus-forming unit (FFU) per ml. Viruses were stored at −80 °C.

2.3. COVID-19 patients and control individuals

We consecutively included in this study 144 adults with SARS-CoV-2 infection confirmed through real-time reverse-transcriptase-polymerase-chain-reaction (RT-PCR) assays of nasal and pharyngeal swabs, in accordance with WHO guidance [20–22]. RT-PCR was performed at San Gerardo Hospital, Monza, and subsequently at the Italian National Institute of Health, Rome, Italy.

Of them, 117 were COVID-19 patients hospitalized from March 2020 to Desio Hospital, ASST-Monza, Italy: 36 had moderate disease presentation (F:M = 13:23, age 65.5 ± 13.5 years, median = 67.12, IQR = 58.6–77.3, min-max range = 32.59–87.48) and 81 had severe disease presentation (F:M = 15:66, age = 69.73 ± 12.99, median = 72.38, IQR = 61.01–79.98, min-max = 33.68–92.27). All were sampled within 10 days from diagnosis (average: 2 days). Subjects were classified as severe if they presented one or more of the following symptoms: respiratory rate (RR) ≥ 30 breaths/min, finger oxygen saturation (SpO2) ≤ 93% at rest, and arterial partial pressure of oxygen (PaO2)/fraction of inspired oxygen (FiO2) ≤ 300 ratio [23,24]. The remaining 27 recruited subjects were SARS-CoV-2 positive patients with mild or minimal symptoms (PACP) not requiring hospitalization (age = 53.48 ± 6.43, median = 54.99, IQR = 47.75–59.15, min-max = 40.56–61.21). Controls were 123 apparently healthy individuals (F:M = 58:65, age = 68.22 ± 9.17, median = 65.46, IQR = 60.1–75.83, min-max = 57–89.99) collected at Desio Hospital before the pandemic outbreak.

2.4. Data collection

Basic information such as age, gender, comorbidities, clinical and laboratory data, chest radiograph (when performed), and outcome (survival or non-survival) was obtained from the electronic medical records of each patient and stored by a password-protected database.

2.5. Antiviral assays

The antiviral activity was determined by the plaque reduction assay. For SARS-CoV-2 experiments, Vero E6 cells were seeded in a 48 well plate, at 6 × 10⁴ cells/well density and incubated at 37 °C overnight. For HCoV-OC43 and RSV, MRC-5 or Hep-2 cells, respectively were first seeded (at 2 × 10⁴ cells/well) in 96 well plates and incubated at 37 °C overnight. The medium was removed from the plates and infection was performed respectively with 10–20 viral PFU per well of SARS-CoV-2 at 37 °C for 1 h, ca. 30 PFU of a stock of HCoV-OC43 at 33 °C for 1 h or ca. 30 PFU of RSV at 37 °C for 3 h, allowing the viruses to attach and enter the cells. After incubation, cells were washed with medium, and overlaid with medium containing 1% carboxymethylcellulose (CMC) with DMEM + 2% FBS, and compound dilutions for SARS-CoV-2 experiments, or with a 1:1 combination of 1.6% SeaPlate Agarose and 2 × DMEM supplemented with different concentrations of compounds. After 72 h of incubation (33 °C, 5% CO2 for HCoV-OC43 or 37 °C, 5% CO2 for SARS-
CoV-2 and RSV), the medium with oxysterols was removed, and the plates were fixed with 3.7% paraformaldehyde (PFA) or 7.5% formaldehyde (Fluka) and stained with crystal violet (Sigma, St. Louis, Mo.). The number of plaques formed was counted. The plaque reduction assay was conducted in 2× replicate in two independent experiments. Blockade of viral infectivity was expressed as mean ± standard error of the mean (SEM). Where possible, half-maximal antiviral effective concentration (EC50) values were calculated by regression analysis using the dose-response curves generated from the experimental data using GraphPad PRISM 7 (GraphPad Software, San Diego, CA, USA). EC50 values were compared using the sum-of-squares F test.

2.6. Virus inactivation assay

Approximately 105 PFU of HCoV-OC43 were incubated with a concentration of 2HP-βCD:27OHC corresponding to EC50 in the antiviral assay. The HCoV-OC43/2HP-βCD:27OHC mixture was incubated for 1 h at 33 °C. A control experiment by treating the viral suspension with the blank formulation (2HP-βCD) was also performed. After the incubation, both treated and untreated viruses were titrated to the non-inhibitory concentration of 2HP-βCD:27OHC and the residual viral infectivity was determined by plaque counting. Statistical analysis was performed using One-Way Analysis of Variance (ANOVA), followed by Bonferroni post-hoc test. Significance was reported for p-value <0.05.

2.7. In vitro cytotoxicity assay

The cytotoxicity assay was conducted with Alamar Blue (Invitrogen) as recommended by the manufacturer’s protocol. Vero E6 cells were seeded at 1 × 103 cells per well in a 96 well plate, and incubated at 37 °C overnight. Then 50 μL of compounds at the indicated concentrations were added to 150 μL of medium (final 200 μL). Plates were incubated at 37 °C for 3 days and then the colorimetric reagent was added (20 μL for 4 h). Measurements from compound-treated or vehicle-treated cells were normalized against those from untreated cells. The half maximum cytotoxic concentration (CC50) was calculated using GraphPad Prism Version 7. Cytotoxicity assay fluorescence readings were normalized for vehicle and percent plotted against dilutions expressed as antilog.

2.8. Cell viability assay

MRC-5 or Hep-2 cells were seeded at a density of 5 × 103/well in 96-well plates and treated the next day with 27OHC, 2HP-βCD:27OHC, or blank formulation at concentrations ranging from 0.07 to 150 μM to generate dose-response curves. Control samples (100% of viability) were prepared by treating cells with culture medium. After 72 h of incubation, cell viability was determined using a Cell Titer 96 Proliferation Assay Kit (Promega, Madison, WI, USA) and following the manufacturer’s instructions. Absorbance was measured using a Microplate Reader (Model 680, Bio-Rad Laboratories, Hercules, CA, USA) at 490 nm. Viability of oxysterol-treated cells is expressed as a percentage relative to cells incubated with culture medium supplemented with equal volumes of ethanol.

2.9. Immunofluorescence

For SARS-CoV-2 analysis Huh7 cells were seeded on coverslips and infected with SARS-CoV-2 the following day at a multiplicity of infection (m.o.i.) of 0.1 PFU/cell. After 1 h, inoculum was removed and fresh DMEM = 2% FBS containing 2HP-βCD:27OHC or 2HP-βCD was added to the cells. After 48 h incubation, cells were fixed with 3.7% PFA, treated with 100 mM glycine and 0.1% Triton X-100, with intermediate washes with PBS. A blocking step was performed at 37 °C for 30 min with 1% bovine serum albumin (BSA) and 0.1% Tween in PBS (blocking solution). The coverslips were then probed with the mSIP-3022 anti-Spike recombinant antibody diluted 1/200 with blocking solution and incubated overnight at 4 °C in humidified container. The reaction was completed by incubating fixed cells with polyclonal anti-mouse antibody conjugated with Alexa Fluor 594 (Molecular Probes, Oregon, USA) diluted 1/500 for 1 h at 37 °C. Coverslips were finally washed and mounted on glass slides using Fluoro-Gel II mounting medium with DAPI (Electron Microscopy Sciences, Pennsylvania, USA) and analyzed with a Zeiss LSM880 confocal microscope. For statistical purposes, 200 ± 10 cells were counted for each condition.

2.10. Clinical laboratory measurements

All clinical laboratory measurements were performed in the course of hospitalization. Count blood cells was performed on whole blood with K3-EDTA vacuum tubes and obtained by Sysmex XN-9000 platform (Sysmex, Germany). Blood chemistries were performed on serum vacuum tubes using COBAS 8000 platform (Roche Diagnostics, Germany).

2.11. Sterols and oxysterols quantification by isotope dilution GC-MS

To a screw-capped vial sealed with a Teflon septum, 0.25 mL of plasma were added together with 500 ng of D7-lathosterol, 50 ng of D6-lanosterol, 50 ng of D7-24S-hydroxycholesterol, 50 ng of D6-25-hydroxycholesterol, 50 ng of D6-27-hydroxycholesterol, 50 ng of D7-7-ketocholesterol, 50 ng of D7-7β-hydroxycholesterol (Avanti Polar Lipids), as internal standards, 50 μL of butylated hydroxytoluene (5 g/L) and 50 μL of K3-EDTA (10 g/L) to prevent auto-oxidation. Each vial was flushed with argon for 10 min to remove air. Alkaline hydrolysis was allowed to proceed at room temperature with magnetic stirring for 60 min in the presence of ethanol 2 M potassium hydroxide solution. After hydrolysis, the sterols were extracted twice with 5 ml hexane. The organic solvents were evaporated under a gentle stream of argon and converted into trimethylsilyl ethers with BSTFA.

Gas chromatography mass spectrometry (GC-MS) analysis was performed on a GC equipped with an Elite column (30 m × 0.32 mm id × 0.25 mm film; PerkinElmer, USA) and injection was performed in splitless mode and using helium (1 ml/min) as a carrier gas. The temperature program was as follows: initial temperature of 180 °C was held for 1 min, followed by a linear ramp of 20 °C/min to 270 °C, and then a linear ramp of 5 °C/min to 290 °C, which was held for 10 min. The mass spectrometer operated in the selected ion-monitoring mode. Peak integration was performed manually, and sterols were quantified from selected-ion monitoring analysis against internal standards using standard curves for the listed sterols. Additional qualifier (characteristic fragment ions) ions were used for structural identification.

Inter-assay CV ranged between 2.3% for lathosterol and 5.3% for 25-hydroxycholesterol. Recovery ranged from 97 up to 104% (5–7).

2.12. Statistical analyses

Continuous variables were expressed as mean ± SD, median, inter-quartile ranges (IQR), min-max range and compared with the ANOVA or Mann-Whitney U test when non parametric distributed.

2.13. Ethics

The study was approved by the Ethical Committee of the Istituto Nazionale Malattie Infettive Lazzaro Spallanzani, Roma and stemmed as a sub-project of the Observational cohort study on the natural history of hospitalized SARS-CoV-2 patients: the STORM trial of the University of Milano Bicocca, Milan, Italy.
3. Results

3.1. 2HP-βCD:27OHC is endowed with antiviral activity against two pathogenic CoVs

The activity of 27OHC against SARS-CoV-2 and HCoV-OC43, was assessed on Vero-E6 and MRC-5 cells, respectively. To improve its solubility and stability, 27OHC was complexed with 2-hydroxypropyl-β-cyclodextrin, a carrier commonly used in drug formulations. Therefore, the complex (2HP-βCD:27OHC) and the carrier alone (2HP-βCD) were tested in parallel to rule out any contribution of the carrier to the antiviral activity.

As shown in Fig. 1 and Table 1, 2HP-βCD:27OHC, but not 2HP-βCD, exerted antiviral activity in a dose-response manner against both SARS-CoV-2 and HCoV-OC43 to maxima of inhibition of 100%, with EC50 values falling in the low micromolar range and with a favourable selectivity index (SI). Conversely, 2HP-βCD:27OHC did not inhibit the infectivity of RSV, an enveloped RNA virus also causing respiratory diseases, thus demonstrating that the antiviral specificity of 27OHC is broad but yet selective.

Time-of-addition experiments were then performed to investigate the step of viral replicative cycle inhibited by 2HP-βCD:27OHC. Two different conditions were used: briefly, cells were treated for 24 h before viral inoculum (pre-treatment protocol) or 3 h after inoculum (post-infection treatment protocol). 2HP-βCD:27OHC showed antiviral activity against the two CoVs both when it was added before and after inoculation (Fig. 2 and Table 2). However, the results show that 2HP-βCD:27OHC has greater efficacy against SARS-CoV-2 when added after infection, while it is more effective against HCoV-OC43 when added before inoculation. Furthermore, we investigated the ability of 2HP-βCD:27OHC to impair infectivity by directly targeting viral particles incubating HCoV-OC43 with 2HP-βCD:27OHC at high effective concentrations (EC50) and then determining the viral titer at dilutions at which the treatment was no longer active when added on cells. As reported in Fig. S1, 2HP-βCD:27OHC was not able to inactivate HCoV-OC43 particles.

The efficiency of SARS-CoV-2 and HCoV-OC43 infection was finally measured respectively in the human cell line Huh7 and MRC-5, in the presence of 2HP-βCD:27OHC. As shown in Fig. 3A and C, and quantified in Fig. 3B and D, 2HP-βCD:27OHC significantly (p<0.001) reduced the number of infected cells 48 h post infection both at 3 μM and 20 μM. By contrast, 2HP-βCD failed to show any anti-CoV activity, showing no significant difference from the untreated control, in terms of number of infected cells.

3.2. Clinical laboratory parameters in moderate and severe COVID-19 patients

The in vitro evidence of effective inhibition of SARS-CoV-2 by the formulation 27OHC-βCD prompted us to carry on an observational cohort study in COVID-19 patients with the aim to monitor 27OHC serum content in the different stages of the disease. As detailed in the Methods section, the groups studied here were: 1) control, 2) pauci-asymptomatic SARS-CoV-2 positive individuals (PACP), 3) moderate COVID-19, 4) severe COVID-19. No age differences were observed between controls and COVID-19 patients, while the subjects of the pauci-asymptomatic group were significantly younger than all the other groups (P<0.001 for all).

With regard to the standard laboratory parameters measured only in the hospitalized patients (see Table 3), HB and HCT, already below the normal values, were significantly lower in severe COVID-19 compared to moderate COVID-19 (P = 0.04 for both). Also serum creatinine was increased both in moderate and severe patients, being significantly higher in the severe COVID-19 group as compared to the moderate COVID-19 one (P = 0.03). Alanine Aminotransferase (ALT) and Lactate Dehydrogenase (LDH) were moderately above the normal range, while Creatine Kinase (CK) was much higher respect to the normal values, in all cases without significant difference between the two groups of patients. C Reactive Protein (CRP), resulted to be markedly elevated in COVID-19 with a tendency to increase in the severe cases, and Procalcitonin (PCT), a marker of sepsis, showed a net average increase in the severe COVID-19 group, that however did not reach statistical significance.

3.3. Sterols quantification in the serum from SARS-CoV-2 infected and control individuals

The main objective of this observational cohort study was indeed the evaluation of the trend of serum 27OHC concentration in hospitalized moderate and severe COVID-19 patients as well as in PACP versus a control group, but a prior overall look at cholesterol metabolism was deemed essential. Of note, serum concentration of cholesterol and precursor sterols lanosterol, desmosterol (Bloch pathway of cholesterol synthesis) and lathosterol (Kandutsch-Russell pathway of cholesterol synthesis) were all significantly reduced in both moderate and severe COVID-19 patients in comparison to controls (P < 0.001) (Fig. 4 and Table S1).

The PACP group showed a cholesterol metabolism picture quite similar to that of the control group, with just a modest but significant reduction in cholesterol and lanosterol serum levels (Fig. 4).
3.4. Oxysterols quantification in the serum from COVID-19 patients, PACP and control individuals

By far, the most interesting finding of the cohort study was the marked reduction of serum 27OHC in both moderate and severe COVID-19 patients compared to controls (P < 0.001 for both) (Fig. 5 and Table S1).

Actually, the serum 27OHC was already significantly reduced in the PACP group, the mean 27OHC decrease being of 17% in PACP group, 30% in the moderate and of 50% in the severe COVID-19 group (Fig. 5). The PACP group was in between controls and COVID groups (Fig. 5 and Table S1). With regard to the other side chain oxysterols physiologically present in human blood, namely 24OHC and 25OHC, only a slight but significant decrease was observed in all three groups of infected subjects, with the only exception of a modest but significant increase of 25OHC in the PACP group. No correlation at all was observed between 24OHC and 25OHC serum levels and the severity of the disease.

Opposite to that of side chain oxysterols was the behaviour in COVID-19 shown by the two B-ring non enzymatic oxysterols of major pathological meaning, namely 7βOHC and 7KC, actually recognized markers of oxidative stress [25,26]. Serum concentration of both oxysterols showed a significant while moderate increment in severe COVID-19 patients as respect to controls (P < 0.001 for both). Serum 7KC but not 7βOHC was significantly increased in the moderate COVID-19 patients as well (P = 0.002). In the SARS-CoV-2 positive but pauci- or a-symptomatic subjects, both markers of oxidative stress did not show any significant difference when compared to the control individuals (Fig. 6).

4. Discussion

The data reported in this study demonstrate that 27OHC blocks the replication in vitro of two human CoVs belonging to the β-coronavirus genus: SARS-CoV-2 and HCoV-OC43. These findings further confirm the broad spectrum of antiviral activity of 27OHC, which has been already demonstrated for herpes simplex virus, rhinovirus, rotavirus and papillomavirus [5]. Since all of these viruses are phylogenetically unrelated, with ample diversity in their replicative cycles and structures, it is unlikely that 27OHC targets specific functions such as viral enzymes or anti-receptors. Moreover, 27OHC does not directly inactivate the viral particle as shown also in previous studies [8] (Fig. S1). The ability to

PACP group, the mean 27OHC decrease being of 17% in PACP group, 30% in the moderate and of 50% in the severe COVID-19 group (Fig. 5). The PACP group was in between controls and COVID groups (Fig. 5 and Table S1). With regard to the other side chain oxysterols physiologically present in human blood, namely 24OHC and 25OHC, only a slight but significant decrease was observed in all three groups of infected subjects, with the only exception of a modest but significant increase of 25OHC in the PACP group. No correlation at all was observed between 24OHC and 25OHC serum levels and the severity of the disease.

Opposite to that of side chain oxysterols was the behaviour in COVID-19 shown by the two B-ring non enzymatic oxysterols of major pathological meaning, namely 7βOHC and 7KC, actually recognized markers of oxidative stress [25,26]. Serum concentration of both oxysterols showed a significant while moderate increment in severe COVID-19 patients as respect to controls (P < 0.001 for both). Serum 7KC but not 7βOHC was significantly increased in the moderate COVID-19 patients as well (P = 0.002). In the SARS-CoV-2 positive but pauci- or a-symptomatic subjects, both markers of oxidative stress did not show any significant difference when compared to the control individuals (Fig. 6).
impair viral entry and/or replication when added up to 24 h before virus inoculum supports the idea that 27OHC modifies cell structures rather than targeting viral components. Indeed, the host-targeting antiviral mode of action has already been reported by Civra et al. [10], showing that 27OHC induces accumulation of cholesterol in the late endosomal compartment resulting in sequestering human rotavirus particles inside these vesicles, thereby preventing cytoplasmic viral replication. Since also CoVs entry into the host cells involves the endocytic pathway [27–29], the anti-CoVs activity of 27OHC appears due, at least in part, to the transient modification of the endosomal membrane composition and function exerted by the oxysterol.

This is especially true in case of 27OHC externally added to the cells, that is in a pharmaceutical mode, in other words as a drug product. Exogenously added 27OHC was proven to almost exclusively accumulate in lipid rafts, as opposed to oxysterols of not enzymatic origin that randomly localize in plasma membranes [12]. Thus, 27OHC is modifying structure and most likely function of these crucial membrane lipid-protein clusters, where by the way the ACE-2 receptor exploited by SARS-CoV-2 to enter the target cells is located [30], and it certainly induces a modification of multivesicular endosome biogenesis, that by lipid rafts is regulated [31]. Further, we very recently observed in HeLa cells a significant 27OHC-dependent down-regulation of cation independent isoform of mannose-6-phosphate receptor (MPRci) [11], a transporter located at late endosomes whose activity appears crucial for all viruses exploiting the endosomal way to enter and diffuse within cells [32–34]. All together, these facts and findings point to the inhibition of virus entry as the primary protective mechanism of 27OHC externally added to cells.

In this relation, very likely appears the involvement of redox reactions at the 27OHC concentration range proven to inhibit SARS-CoV-2 and CoV-OC43 replication, since similar oxysterol’s amounts have been previously demonstrated to transiently increase the level of oxidant species in human promonocytic cells through the activation of NADPH oxidase and the modulation of mitochondrial membrane potential [35].

Fig. 3. Infectivity inhibition as assessed by immunofluorescence experiments. Huh-7 (A) and MRC-5(C) cells were infected with SARS-CoV-2 and HCoV OC43 in the presence of 2HP-jCD:27OHC, then fixed at 48 h post-infection and stained with DAPI and specific antibodies. Panels B and D show respectively the number of SARS-CoV-2 and HCoV OC43 positive cells. On the y axis, this value is expressed as % of the virus positive cells as compared to DAPI positive cells. Error bars represent the SEM of 2 independent experiments.
Heat Shock Protein 60 (HSP60) [41], a chaperone molecule of MHC classes I and II molecules [38, 39] or by activating the TLR4/NF-kB inhibitor [36].

The pro-autophagic effect of 27OHC observed in human promonocytic degradation and closely interacting with innate immunity [37]. Notably, elimination of viral pathogens by delivering viral particles for lysosomal phagy [36], a cellular degradation process in principle favouring the mitochondrial origin, recognized to play an important role in the intercellular immune network [42]. Finally, all immune cells express the oxysterols’ receptors Liver X (LXRs) [43], but their activity could be modulated by molecules like 27OHC still has to be elucidated.

The physiological nature of 27OHC and its potential role as first line constitutive effector of the antiviral defences of human body prompted us to analyse the 27OHC serum levels in COVID-19 patients at different stages of disease progression.

Standard laboratory findings achieved in hospitalized patients were consistent with previous reports on COVID-19 [44-47]. Of particular interest were the low or very low serum cholesterol levels observed in moderate and severe COVID-19 patients, respectively (Fig. 4 and Table S1), indicating a severe impairment of cholesterol metabolism. Serum cholesterol has just been shown to be significantly decreased in

Of particular interest were the low or very low serum cholesterol levels observed in moderate and severe COVID-19 patients, respectively (Fig. 4 and Table S1), indicating a severe impairment of cholesterol metabolism. Serum cholesterol has just been shown to be significantly decreased in
COVID-19 patients in direct relation with the severity of the disease, with data highly consistent with those obtained in this study [48], while the reduction of the main sterol precursors of cholesterol in COVID-19 has not been reported in the literature yet. A big impairment of cholesterol metabolism, at least in severe COVID-19 patients, was actually expected since a net reduction of cholesterol biosynthesis was described as associated with massive acute phase reaction [49]. Certainly remarkable is the fact that, despite such a profound derangement of cholesterol metabolism in COVID-19, of the three cholesterol oxidation products of enzymatic origin physiologically present in human blood, i.e. 24OHC, 25OHC and 27OHC, only 27OHC showed a pronounced decrease whose intensity tightly correlated to the disease progression (Fig. 5).

The drop in 27OHC serum concentration appeared to be a specific event, since 24OHC was slightly reduced only in moderate (P = 0.036) and severe (P = 0.029) COVID-19 cases, while 25OHC exhibited a small but significant decline only in severe patients (P = 0.018) and it was even slightly increased in the PACP group (P = 0.033 compared to controls, P < 0.001 compared to severe COVID-19 patients), possibly as a consequence of a transiently beneficial INFγ-mediated induction of cholesterol-25-hydroxylase (Cyp27A1) [6,50].

Still with regard to the quantification of oxysterols in SARS-CoV-2 infected subjects, a consistent while moderate increase of serum 7-keto- and 7β-cholesterol, recognized in vivo markers of oxidative stress, was observed in COVID-19 patients but not in pauci- and asymptomatic individuals. Actually, an expected finding, because of the serious inflammatory state afflicting those patients, but, to our knowledge, a not yet reported observation.

It is not easy, at present, to identify the reason for the detected selective drop in the 27OHC serum level during SARS-CoV-2 infection in the course of COVID-19. The most plausible hypothesis is that a progressive “mitochondrial stress” would occur at systemic level in those pathological conditions, and that such an impairment would affect the activity of the ubiquitous mitochondrial 27-cholesterol hydroxylase (Cyp27A1) [51], which is the enzyme that converts cholesterol to 27OHC.

Whatever is the actual cause of the progressive reduction of 27OHC in the course of COVID-19, this observational clinical study definitely suggests the opportunity of counteracting such an event, in order to reinforce or reintegrate the antiviral defence system with the administration of suitably formulated 27OHC endowed with antiviral activity.

Notably, the inhibitory activity also shown against CoV-OC43, which is responsible for 10–20% of the cases of common cold together with CoV-229E [52], further highlights the broad antiviral effect of 27OHC, thus opening interesting perspectives on its consideration in future strategies against emerging coronaviruses.

5. Conclusions

In conclusion, this report demonstrates the antiviral activity of 27OHC against SARS-CoV-2 and one related β-coronavirus and shows the dramatic decrease of physiological levels of 27OHC in severe COVID-19. Although the latter observation deserves further investigation, the identification of 27OHC as a novel physiological antiviral with a broad spectrum against β-coronaviruses may be of great importance for the treatment of SARS-CoV-2 infections and possible future epidemics.

Declaration of interests

Andrea Civra, David Lembo, Giuseppe Poli are the founders of Panoxyvir Ltd., a start-up developing the use of specific oxysterols as broad antiviral agents. Panoxyvir Ltd., together with ICGEB, the affiliation of...
the fourth inventor Alessandro Marcello, filed on April 2020 an application to patent the use of 27-hydroxycholesterol in the treatment and/or prevention of diseases caused by Coronaviruses (app n. 102020000008977). Panoxyvir did not provide any financial support to this study. All authors declare no other competing financial interests or conflicts of interest.
